 - Integer Programming formulations and Conjectures

Extremal Graph Theory

How large or small can a graph parameter be under a given set of conditions?

Turán's theorem (special case): The max number of edges in a triangle-free graph G with n vertices is $\lfloor n^2/4 \rfloor$; it is achieved by a balanced complete bipartite graph.

Edge-extremal Problem

How many edges can a graph have at most, under restrictions on its maximum degree and matching number?

max *number of edges*
s.t. maximum degree $\leq d$
 matching number $\leq m$

max $|E(G)|$
s.t. $\Delta(G) \leq d$
 $\nu(G) \leq m$

$d(1)=3$
 $d(6)=4$
 $\Delta(G)=d(9)=6$

$\nu(G) = 4$

Edge-extremal Problem

A graph of degree at most d and matching number at most m and having a maximum number of edges is called *(edge-) extremal*.

Q1: Find the opt value

Q2: Find / characterize all extremal graphs

Q3: In which cases the extremal graphs are unique?

Edge-extremal Problem

$$\begin{aligned} \max & |E(G)| \\ \text{s.t.} & \Delta(G) \leq d \end{aligned}$$

$$\begin{aligned} \max & |E(G)| \\ \text{s.t.} & v(G) \leq m \end{aligned}$$

For $|E(G)|$ to be finite, we need to bound both $\Delta(G)$ and $v(G)$.

Literature

- Erdős, Rado, 1960 : a more general problem about set systems
- Chvátal, Hanson, 1976 : answers our question for general graphs and finds some extremal graphs (LP ideas and Berge's matching formula)
- Balachandran, Khare, 2009 : alternative proof with structural approach → construction of extremal graphs (but no information about their uniqueness apart from a few cases)

Edge-extremal General Graphs

$\mathbb{M}_{\mathbf{C}}(d, m)$: All graphs G in the class \mathbf{C} s.t. $\Delta(G) \leq d$ and $v(G) \leq m$

$f_{\mathbf{C}}(d, m)$: maximum number of edges in a graph in $\mathbb{M}_{\mathbf{C}}(d, m)$

: size of an edge-extremal graph in \mathbf{C} (for d and m)

Vizing's Theorem: $\chi'(G) \leq \Delta(G) + 1$

$$|E(G)| \leq (\Delta(G) + 1)v(G) \leq dm + m$$

This upper bound is met when some divisibility conditions for d and m hold, and we are pretty close otherwise.

Edge-extremal General Graphs

\mathcal{GEN} : Class of general graphs

Thm (Balachandran, Khare, 2009): $f_{\mathcal{GEN}}(d, m) = dm + \left\lfloor \frac{d}{2} \right\rfloor \left\lfloor \frac{m}{\lceil \frac{d}{2} \rceil} \right\rfloor$

Moreover, an edge-extremal graph can be obtained by taking

disjoint union of **d-stars**, **complete graphs K_{d+1}** (if d even)

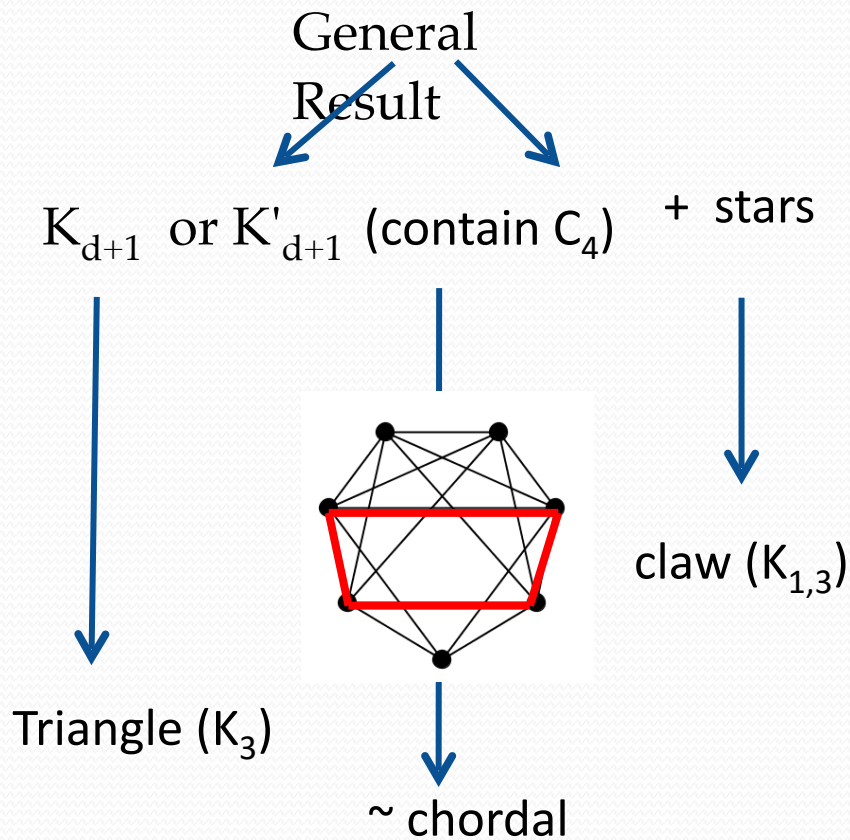

An edge-extremal graph for $d=4, m=5$

is K

An edge-extremal graph for $d=5, m=5$

What if we restrict the structure of extremal graphs? Can the same upper bound be still achieved?

- (Dibek, E., Heggernes, 2017):
 d small enough \rightarrow $\text{Max } |E(G)|$ remains the same; d large enough \rightarrow $\text{max } |E(G)|$ decreases
- (Blair, Heggernes, Lima, Lokshtanov, 2020) (more restricted than C_4 -free graphs): the general bound not achieved.
- (Maland, 2015): Bipartite graphs, split graphs, unit interval graphs
- **Open question:** T-free graphs?
 $f_{\Delta}(d, m) = ?$

Edge-extremal T-free graphs with $d \geq m$

- **Thm:** $f_{\Delta}(d, m) = dm$ for $d > m \geq 1$. (m many d-stars)

- **Thm:** $f_{\Delta}(1, 1) = 1$ and $f_{\Delta}(d, d) = d^2 + 1$ for $d \geq 2$.

A_d : Blow-up of C_5

Edge-extremal T-free graphs with $d < m$

- **Thm:** $f_{\Delta}(1, m) = m$ for all $m \geq 1$. (m independent edges)

→ Assume $d \geq 2$

- **Key Result:** Let G be an edge-extremal T-free graph with $\Delta(G) \leq d$, $v(G) \leq m$ having a maximum number of d -star components. Then every component H of G that is not a d -star
 - **factor-critical** (thus $|V(H)| = 2v(H) + 1$)
 - with $d \leq v(H) \leq Z(d)$, and
 - edge-extremal for d and $v(H)$ ($|E(H)| = f_{\Delta}(d, v(H))$)

Edge-extremal T-free graphs with $d < m$

- **Def:** For any $d \geq 2$, let $Z(d)$ be the smallest natural number n s.t. there exists a d -regular (if d is even) or almost d -regular (if d is odd) T-free and factor-critical graph G with $v(G) = n$.
- **Lemma:** For every $d \geq 2$, the value $Z(d)$ and a T-free factor-critical (almost) d -regular graph B_d with matching number $Z(d)$ exist.
- **The value of $Z(d)$ is crucial:**
 - $Z(d)$ known for $d \leq 6$;
 - $Z(d) = \lfloor 5d/4 \rfloor$ if $d \geq 2$ even;
 - $Z(d) = \lfloor 5(d-1)/4 \rfloor \leq Z(d) \leq \lfloor 5(d+1)/4 \rfloor$ if $d \geq 2$ odd.

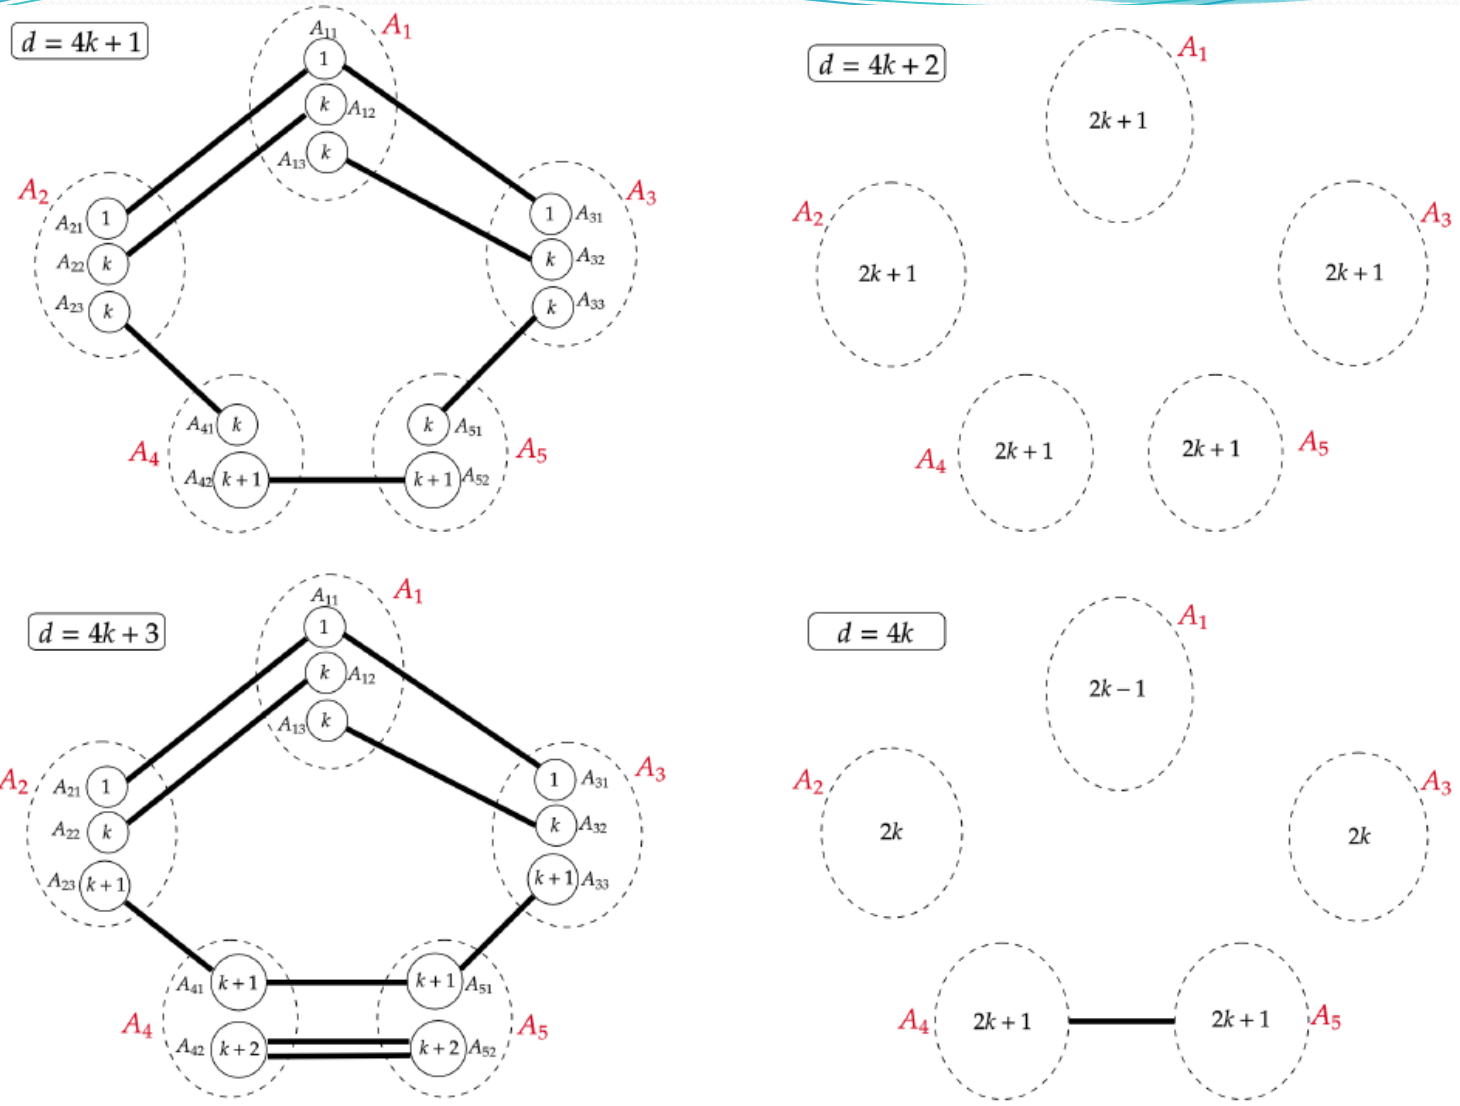

Figure 2: The graph B_d for $d \geq 2$ depending on $d \pmod{4}$.

Edge-extremal T-free graphs with $d < m$ and $Z(d) \leq m < 2d$

Thm (idea): Take as many B_d as possible, complete the matching number with d -stars $\rightarrow dm + \lfloor d/2 \rfloor$ edges

$$m = kZ(d) + r$$

Matching number = $k Z(d)$
edges = $(2Z(d) + 1) d / 2$

r many d -stars
matching number = r
edges = $(m - Z(d))d$

Main Theorem

Let d and m be natural numbers with $d \geq 2$, let k and r be nonnegative integers such that $m = kZ(d) + r$ with $0 \leq r < Z(d)$. Then, for all the cases with

- $d \geq m$
- $d < m$ and $d \leq 6$
- $d < m$ and $Z(d) \leq m < 2d$

we have,

$$f_{\Delta}(d, m) = \begin{cases} dm + k \lfloor d/2 \rfloor & \text{if } r < d, \\ dm + k \lfloor d/2 \rfloor + r - d + 1 & \text{if } r \geq d, \end{cases}$$

where an extremal graph can be constructed as the disjoint union of k copies of B_d and

(i) A_d if $r \geq d$,

(ii) r copies of d -stars if $r < d$.

Deviation from general extremal graphs

$$h_{\Delta}(d, m) = \begin{cases} 0, & \text{if } m < \lfloor d/2 \rfloor, \\ \lfloor d/2 \rfloor, & \text{if } \lfloor d/2 \rfloor \leq m < d \\ d, & \text{if } d = m \text{ and } d \text{ is even,} \\ \lfloor d/2 \rfloor, & \text{if } d = m \text{ and } d \text{ is odd,} \\ 0, & \text{if } 1 = d < m, \\ m - \lfloor m/2 \rfloor, & \text{if } 2 = d < m, \\ \lfloor m/2 \rfloor - \lfloor m/3 \rfloor, & \text{if } 3 = d < m, \\ 2\lfloor m/2 \rfloor - 2\lfloor m/5 \rfloor, & \text{if } 4 = d < m \text{ and } m + 1 \text{ is not divisible by 5,} \\ 2\lfloor m/2 \rfloor - 2\lfloor m/5 \rfloor - 1, & \text{if } 4 = d < m \text{ and } m + 1 \text{ is divisible by 5,} \\ 2\lfloor m/3 \rfloor - 2\lfloor m/6 \rfloor, & \text{if } 5 = d < m \text{ and } m + 1 \text{ is not divisible by 6,} \\ 2\lfloor m/3 \rfloor - 2\lfloor m/6 \rfloor - 1, & \text{if } 5 = d < m \text{ and } m + 1 \text{ is divisible by 6,} \\ 3\lfloor m/3 \rfloor - 3\lfloor m/7 \rfloor, & \text{if } 6 = d < m \text{ and } m + 1 \text{ is not divisible by 7,} \\ 3\lfloor m/3 \rfloor - 3\lfloor m/7 \rfloor - 1, & \text{if } 6 = d < m \text{ and } m + 1 \text{ is divisible by 7,} \\ \lfloor d/2 \rfloor, & \text{if } d \geq 7 \text{ and } Z(d) \leq m < 3\lceil d/2 \rceil, \\ 2\lceil d/2 \rceil, & \text{if } d \geq 7 \text{ and } 3\lceil d/2 \rceil \leq m < 2d. \end{cases}$$

Integer Programming formulation

- **Open cases:** $7 \leq d < m$ and either $m < Z(d)$ or $m \geq 2d$
- **Reminder (Key result):** Every component H of an edge-extremal graph G that is not a d -star is edge-extremal T -free graph for d and $v(H)$ where $d \leq v(H) \leq Z(d)$ →
extremal components
- **Decision variable** $x_i = \#$ of extremal components of G whose matching number is i where $d \leq i \leq Z(d)$.
- How many of each extremal component with matching number i (x_i) for each $d \leq i \leq Z(d)$?
- How many d -stars?

Knapsack formulation

$$\sum_{i=d}^{Z(d)} ix_i \leq m$$

$$f_{\Delta}(d, m) = d \left(m - \sum_{i=d}^{Z(d)} ix_i \right) + \sum_{i=d}^{Z(d)} f_{\Delta}(d, i) x_i$$

utilities

Extremal components

$$m - \sum_{i=d}^{Z(d)} ix_i$$

d-stars

$$\max dm + \sum_{i=d}^{Z(d)} (f_{\Delta}(d, i) - di) x_i$$

utilities

$$\text{subject to } \sum_{i=d}^{Z(d)} ix_i \leq m$$

volumes

$$x_i \geq 0, x_i \in \mathbb{Z}$$

Efficiently
solved

Conjectures for open cases

- **Conj 1:** Main thm also holds for $6 < d < m < Z(d)$; for i s.t. $6 < d < i < Z(d)$ we have $f_{\Delta}(d, i) = di + i - d + 1$.
- **Prop:** If Conj 1 true then (using $f_{\Delta}(d, Z(d)) = dZ(d) + \lfloor d/2 \rfloor$) IP equivalent to the following formulation which admits an opt. sol. where $x_{Z(d)}$ is maximized and there is at most one other extremal component with smaller matching number.

$$\max \lfloor d/2 \rfloor x_{Z(d)} + \sum_{i=d}^{Z(d)-1} (i - d + 1)x_i$$

$$\text{subject to } \sum_{i=d}^{Z(d)} ix_i \leq m$$

$$x_i \geq 0, x_i \in \mathbb{Z}$$

Interpretation → New conjecture

- If Conj 1 holds, $f_{\Delta}(d,i)$ edges can be achieved by taking the graph B_d as much as possible and adding either one extremal component for d and r ; or r many d -stars, depending on $r \geq d$ where $r =$ remainder of m when divided by $Z(d)$. (Just like in the main Thm)

- **Conj 2:** . *Let $m = kZ(d) + r$ for some $0 \leq r < Z(d)$. Then, we have*

$$f_{\Delta}(d, m) = \begin{cases} dm + k \lfloor d/2 \rfloor & \text{if } r < d \\ dm + k \lfloor d/2 \rfloor + r - d + 1 & \text{if } r \geq d. \end{cases}$$

- **Conj 3:** For $d \geq 21$ and odd, we have $Z(d) = \lfloor 5(d+1)/4 \rfloor$.

New IP for extremal components $f_{\Delta}(d,i)$

- IP formulations for constructing extremal components for i s.t. $6 < d < i < Z(d) \rightarrow$ missing parameters for Knapsack

- Decision var. x_{ij} = edge ij exists or not

Max $\sum x_{ij}$ Key Lemma

s.t. T-free

$$\Delta(G) \leq d$$

$$v(G) \leq m$$

x_{ij} binary

$$\begin{aligned} \max \quad & \sum_{i,j \in V} x_{ij} \\ \text{s.t.} \quad & x_{ij} + x_{jk} + x_{ik} \leq 2 \quad \forall i, j, k \in V \\ & \sum_{j \in V} x_{ij} \leq d \quad \forall i \in V \\ & x_{ij} \in \{0, 1\} \quad \forall i, j \in V \end{aligned}$$

Using IP for
constructing graphs
with structure

High symmetry!

Methodology

1. **Basic Formulation + CPLEX symmetry breaking 5**
2. **Orbital Branching** to eliminate isomorphisms in the branch&cut tree: find symmetry / automorphism groups -> variable orbits and constraint orbits (equivalence classes). Reducing symmetry
3. **Iterative formulation**: Set all degrees to d , then all but one to d , etc. searching for a feasible solution, until $UB=LB$. Reducing the feasible region.
4. **Combination** of Orbital Branching and Iterative Approach

Computational experiments

- Intel(R) Core(TM) i7-9750H CPU @ 2.60GHz with 32 GB RAM using CPLEX 20.1.0 on 10 threads.
- CPLEX 20.1.0 with C++ to implement the methods
- A limit of 1800 seconds for each run
- Orbital Branching and Iterative Method with callback mechanism of CPLEX. Orbits found by nauty 2.7r3 software library to compute automorphism groups [McKay, Piperno, 2014]

Main findings with IP

- We construct all **extremal components** for $d=7,8,9,10$ and $d < m < Z(d)$ with IP + some for $d=11,12$ and 13.
- We solve the Knapsack Formulation for $d=7,8,9,10$ and any m value
- All our findings support Conjectures 1, 2.
- All extremal graphs have a max number of $x_{Z(d)}$ and at most one other extremal component.
- As a byproduct (checking the degrees), we obtain new values for $Z(d)$: $Z(7)=9$, $Z(9)=13$, $Z(11)=15$, and $Z(13)=17$. (By definition of $Z(d)$ and checking the degrees)

Bottlenecks:

- 1) Computing the orbits
- 2) Decreasing the UB

Pattern for extremal components suggested by IP

- Prop:** For all $i = d + t$ such that $d < i < Z(d)$, the graph $B_{d,d+t}$ is an extremal graph if Conjecture 1 holds (with $d_i + i - d + 1$ edges. $\Lambda(B_{d,d+t}) = d$ and $v(B_{d,d+t}) = d + t = i$)

- H independent set
- F complete bipartite – t distinct perfect matching
- Opposite parts of F and H are completely linked

Generalizes the extremal graph A_d for $f_{\Delta}(d, d)$

Conclusion

- IP methods
 - shed some light on the open cases
 - provides more motivation to search for a formal proof
 - but they can never settle all open cases
- Structural proofs for the conjectures require more powerful techniques
- Nice combination of IP and structural graph theory
- Opens the way to use IP to construct graphs with desired properties

Future Work

- What if we forbid **k-star**? ($k \geq 4$) Can we find an explicit formula in terms of d , m , and k , for the maximum number of edges that a graph G can have where $\Delta(G) \leq d$, $v(G) \leq m$ and where G does not contain k -star as an induced subgraph?
- What if we forbid **k-clique**? What is the maximum number of edges of a graph G where $\Delta(G) \leq d$, $v(G) \leq m$ and $\omega(G) < k$?
- What if we require **connectivity** for general edge-extremal graphs?

Thank you for listening

A question inspired by IP

- IP for extremal components: $|V(H)| = 2v(H) + 1$ but we do not explicitly force that H is factor-critical.
- However, it turns out that all extremal components resulting from IP are factor-critical.

$$\begin{aligned} & \max \sum_{i,j \in V} x_{ij} \\ \text{s.t. } & x_{ij} + x_{jk} + x_{ik} \leq 2 \quad \forall i, j, k \in V \\ & \sum_{j \in V} x_{ij} \leq d \quad \forall i \in V \\ & x_{ij} \in \{0, 1\} \quad \forall i, j \in V \end{aligned}$$

QUESTION: Is it true that a triangle-free extremal graph G with matching number m and maximum degree d such that $d < m < Z(d)$ and having $2m + 1$ vertices is factor-critical?

Relation to Ramsey Numbers

Observation: Let G be a graph, let $L(G)$ be the line graph of G , and let $d \geq 4$ and $j \geq 1$ be two integers. Then G has a vertex of **degree at least d** if and only if $L(G)$ has **a clique of size d** . Moreover, G has a **matching of size m** if and only if $L(G)$ has **an independent set of size m** .

Graph G

Graph $L(G)$
